CASE PRESENTATION

79-year-old African American male presented with blurry vision and progressive vision loss in the left eye for about 6 years. Patient medical and ocular history was unremarkable, though last medical exam was more than 20 years ago.

DISCUSSION

Compressive lesion should always be a differential diagnosis with findings of optic atrophy and progressive vision loss. Visual field should be performed in the presence of unexplained vision loss and is often helpful in determining the next step in the management plan.
